CustomerList.java

The class **CustomerList** creates and manages a customer list as a one-dimensional array of objects of the **Customer** class.

Define the class **CustomerList** containing a 1D array **myList** (e.g., 50 elements). Each position in the array stores an object of type Customer.

CustomerList contains (defines) the following methods:

1. **`InsertCustomer`**: stores a customer's data in the list (array).
2. **LookupCustomer**: searches the list for a customer based on their code and displays their name and registration date. If the customer does not exist in the list, it displays an appropriate message.
3. **`DisplayList`**: displays the details of all customers present in the list.

```
class CustomerList {
    private Customer [] myList = // Fill your code
here
    private int length = 0;
    InsertCustomer(Customer newCustomer){
        // Fill your code here
    }

    void LookupCustomer(String code) {
        // Fill your code here
    }

    void DisplayList() {
        // Fill your code here
    }
}
```

Complete the file **CustomerList.java**

Every program must compile and run from the command line (not through an IDE).
